

[Weighted blanket for securing infants during sleep.]

Abstract

The weighted blanket is used for securing infants and dampening the effect of being startled and/or twitching during sleep. The blanket is placed on top of the infants while the bottom flap is at the bottom of the infant to prevent the blanket from flipping on top of the infant's face. The mesh fabric is breathable so there is a less chance of suffocation. Both the weighted blanket and the bottom flap may be placed on top of the infant if preferred. The weights maybe removed from the blanket pouches for other uses such as pillows.
